PDPs have a simple structure and are easily manufactured. In addition, PDPs have excellent luminous efficiency, luminance, contrast, viewing angle, and color purity, and thus are widely used for displaying images. A PDP includes two glass substrates, a discharge gas, and electrodes. The glass substrates include a display area in which the discharge gas is sealed between the two glass substrates, and a non-display area in which the driving circuit, etc. are formed. In addition, the electrodes include first and second electrodes (i.e., a sustain electrode and a scan electrode) that are formed on the upper substrate, and first and second sustain electrodes (i.e., a sustain sustain electrode and a sustain scan electrode) that are formed on the lower substrate. FIG. 1 is a cross-sectional view of a conventional PDP. As shown in FIG. 1, in the conventional PDP, the first and second sustain electrodes 22 and 22' are formed on an upper substrate 20, and a first electrode 14 is formed on the lower substrate 10. A PDP that is used for displaying images typically includes a plurality of display electrodes 14 and 22, each display electrode 14 and 22 having a plurality of discharging cells corresponding to the number of scanning and sustaining electrodes (i.e., a scan electrode 14, a sustain electrode 22, and a scan electrode 22', which are illustrated as a grid in FIG. 1). The conventional PDP having the above configuration requires that
